

## **ABSTRACT**

Dispensing apparatus for dispensing flowable materials onto an object. A sub-assembly of the dispensing apparatus is releasably receivable within a casing and comprises: (i) a resiliently deformable collar portion for receiving an opening of a container; (ii) a one-way input valve (see Fig. 1); a one-way output valve; and a conduit separating the valves. A cradle member having cam surfaces is pivotably connected to the casing and is provided with supporting surfaces adapted to receive the object. A manual force applied by a user in a direction corresponding to the longitudinal axis of the object causes projections on the output valve to move up the cam surfaces. In this way, the volume between the inlet and outlet valves is reduced and flowable material is directed onto the object.
